(54) METHOD OF AND APPARATUS FOR TESTING THE AUTHENTICITY OF PIECES OF PAPER

(71) We, NATIONAL REJECTORS INC. G.m.b.H., a German Body Corporate, of 215, Buxtehude, Zum Fruchthof 6, Germany, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:—

The invention relates to a method of and apparatus for testing the authenticity of pieces of paper, particularly but not exclusively bank-notes which contain fluorescent material, for example particles or fibres.

In known processes for testing the authenticity of pieces of paper, such as banknotes, the pieces of paper to be tested are checked with respect to the printing inks used and to the design printed on their surfaces, with reference to a standard piece of paper. Checks have also been made on the watermark in the paper, a safety thread incorporated in the paper, or the type of paper used.

All the above mentioned processes, however, are unsatisfactory as regards their ability to prevent fraud. It has been found that falsifications are most likely to be detected if the pieces of paper are tested with respect to features which have been introduced into the body of the paper during production of the paper used, such features being distinct and distinguishable from features subsequently added to the individual piece of paper. For example German banknotes have been printed for some time on paper with fluorescent fibres embedded therein, the fluorescent fibres in this case being mainly of a thickness only a little

less than that of the paper used.

It is the aim of the present invention to provide for testing to establish the presence of such fluorescent material incorporated in the paper, and to distinguish the

fluorescent material from fluorescent material subsequently applied to the piece of paper.

Thus, according to the present invention, there is provided a method of testing the authenticity of pieces of paper containing fluorescent material, in which the paper is moved past a light source the radiation of which excites the fluorescent particles, and the fluorescence radiation emanating on that side of the paper which is averted from the the light source is measured by means of a photo-receiver which is sensitive only to that radiation, the result of the test being indicated by the output of the photo-receiver.

It is possible to distinguish between an imprinted fluorescence layer and fluorescent material distributed in the volume of paper. If, for instance, the imprinted layer is situated on that side of the piece of paper which faces towards the light source, then the exciting radiation may well excite the fluorescent material to emit the fluorescence spectrum, but this radiation does not reach the photo-receiver situated on the other side because it is essentially absorbed by the material of the paper. on the other hand, the imprinted layer is present on that side of the paper away from the light source, then the exciting radiation emitted from the light source does not effectively excite the applied fluorescent material to emit the fluorescence radiation because it is absorbed in the paper layer. In neither case, therefore, is the photo-receiver excited to produce an indicative signal.

With the fluorescent material embedded in the paper and of thickness comparable to that of the paper, a portion of the exciting radiation emitted from the light source is likewise absorbed but the intensity of radiation impinging on the fluorescent ma-

55

65

70

75

80

85

terial suffices to excite the material to fluorescence as there is only a thin layer of paper covering the fluorescent material on each side, which thin layer absorbs the fluorescence radiation to only a minor extent so that the photo-receiver registers the radiation and produces an indicative signal.

As the photo-receiver is responsive only to the spectrum of emission emitted from 10 the fluorescent material, the measuring is not affected by the exciting radiation, the wave length of which is shorter than that of the fluorescence radiation. It is to be noted here that fluorescent substances having a relatively narow spectral band of excitation and emission are comonly chosen for use.

In order to increase the sensitivity of the process, the fluorescence radiation emanating from that side of the paper which faces the light source is preferably also measured by means of a photo-receiver which is sensitive only to that particular radiation to provide a further indicative output. This is advantageous because the thickness of the fluorescent material is not uniform and some of the material may be situated more closely beneath the illuminated surface and some more closely beneath the other surface.

In order to perceive cracks or seams which may easily occur when fluorescent material is applied to the paper after it has been produced, provision is preferably made for the radiation passing through the paper to be measured by means of a photoreceiver which is sensitive only to that exciting radiation and the size of the associated signals is additionally taken into consideration when accepting or rejecting the piece of paper. When a crack or inaccurate seam is present the intensity of the light passing through is high, so that the resulting signal will have a considerable amplitude level or show a high pulse count.

In order to increase still further the effec-45 tiveness of the testing operation, the signals arising from the fluorescence radiation emanating from that side of the paper which is averted from the light source may be counted, and the piece of paper is acepted when 50 a certain minimum number of pulses is reached. In this way the test cannot be deceived by the presence of a single fluorescent particle introduced into the paper. As during production of the paper the fluor-55 escent material is uniformly dispersed in the paper a uniform distribution of fluorescent material can be taken to be present over the area of the piece of paper.

In the movement of the paper past the 60 light source, several portions of the material are effective one after another to emit a fluorescence radiation so that a minimum number of signals may be determined to be characteristic for each type of paper for 65 the purpose of the testing of the paper.

The piece of paper under test is not acceptable if this minimum number is not reached.

The examination procedure may be further improved by basing the acceptance of the piece of paper upon the coincident occurrence of the signals resulting from the fluorescence radiations emanating from both sides of the paper. Distinction be-tween embedded fluorescent material and subsequently applied fluorescent material is achieved with greater assurance if the fluorescence radiations are measured as they are emitted simultaneously from both sides of the piece of paper.

Provision is also desirably made for 80 simultaneously detecting the exciting radiation through the piece of paper to test the transparecency of the paper in order to recognize a lacking watermark, a missing safety thread, a wrong density of the paper or spots of applied adhesives in the paper. For this purpose the signals resulting from the exciting radiation passing through are discriminated, and rejection of the piece of paper is effected when the lower threshold is not reached or when the upper threshold is exceeded.

The characteristic features of the fluorescent substances include not only the absorption and emission spectra but also the duration of afterglow. The excitation and duration of afterglow. registration of the fluorescence radiation may therefore be done simultaneously or at times spaced by an interval. In the latter case, additional use may be made of the 100 afterglow period as a parameter of testing.

According to another aspect of the invention there is provided apparatus for testing the authenticity of pieces of paper containing fluorescent material with the aid of a 105 light source the radiation of which excites the fluorescent particles, and including means for moving the paper spread-out in a plane past the light source, the light source and a photo-receiver sensitive to the fluor- 110 escence radiation emitted from the particles being arranged on opposite sides of the plane. To increase the accuracy in testing, another photo-receiver sensitive to the emitted fluorescence radiation is preferably 115 arranged on the side of the plaane on which the light source is located. The testing apparatus may further include a photoreceiver which is sensitive only to the exciting radiation, arranged on the other side 120 of the plane from the light source. The additional photo-receiver for the fluorescence radiation and the additional photoreceiver for the exciting radiation extend the testing of the paper for greater assur- 125

Preferably, the light source, and the photo-receiver for the fluorescence radiation arranged on the other side of the plane, are arranged in such a manner that 130

the fields of irradiation and view coincide. In this case, the immediate emission of the fluorescence spectrum on excitation is measured. The arrangement may also be selected to be such that the fields of irradiation and view do not coincide. So that the two photo-receivers which are sensitive only to the fluorescence radiation may emit coincident signals, provision is made for the fields of view of these two photo-receivers to coincide. In order to obtain significant signals it is desirable that the fields of view of the light source and the photo-receiver comprise narrow strips extending prefer-15 ably length-wise or width-wise and in particular over the entire length or width of the piece of paper.

The outputs of the photo-receivers are processed in a control unit. The control unit preferably includes a coincidence circuit, a counting circuit, a discriminator circuit and a trigger means. As most of the photo-senstive structural elements available on the market have too broad a band-width, the photo-receivers are composed of photo-sensitive structural elements and narrow-band type filters which allow to pass only the exciting emission and fluorescence emission spectrum, respectively.

If, in the proposed testing apparatus, differences in brightness are utilized to perform the testing operation, it is not necessary that an exact image be formed of the piece of paper on the sensitive surface of the photo-receiver. Photo-receivers useful for the measurement include semiconductor photo-cells, alkali metal photo-cells, or secondary emissive photo-multipliers.

The invention will now be further des-

40 cribed, by way of example, with reference to the accompanying drawings, in which:-Figure 1 is a cross-sectional view of a bank-note with fluorescent fibres embedded

30

Figure 2 is a cross-sectional view of a 45 bank-note with fluorescent particles applied to the outer surface thereof;

Figure 3 is a perspective view of the apparatus embodying the invention;

Figure 4 is a side view of the apparatus embodying the invention and

Figure 5 is a block circuit diagram of the photo-receivers conencted with a control unit.

The testing process in accordance with the invention will now be described referring firstly to Figures 1 and 2. Fluorescent fibres F are incorporated in the bank-note B, the diameter of said fibres being almost as large 60 as the thickness of the piece of paper constituting the bank-note B. The fibres may typically be 3 to 4 mm in length and the thickness of the fibres is not necessarily uniform. Assuming that, as shown in Figure 65 1, the exciting radiation AS is incident from

above, a portion of this radiation is absorbed in the paper layer between the outer surface of the bank-note B and the surfaces of the individual fibres F. This layer is however so thin that the incident radiation AS excites the fluorescent fibres F to emit the fluorescence emission FS. The fluorescence emission FS is of longer wave length than the exciting radiation AS. This is indicated by the difference in sinuosity of the arrows of radiation although the difference in wave length need not be so considerable as the shown arrows suggest. The emitted fluorescence radiation FS passes through a small thicknes of paper in which only a small portion is absorbed. On both sides of the bank-note, therefore, a fluorescence radiation occurs under excitation by the exciting radiation AS.

This distribution of radiation cannot be detected in a bank-note such as that shown in Figure 2, which has its surface imprinted with fluorescent particles. Assuming firstly that within the bank-note of Figure 2 the exciting radiation is incident from above. The exciting radiation excites the particles P to emit the fluorescence radiation FS. This fluorescence radiation, however, can be observed only above the upper side of the paper, because the downwardly emitted fluorescence radiation FS is essentially absorbed in the body of the bank-note B. The space below the paper is therefore essentially free from fluorescence radiation. If in Figure 2 the exciting radiation impinges on 100 the bank-note from below, it is absorbed in the body of the bank-note, so that the fluorescent particles P present on the upper side are not excited to emit the fluorescent spectrum. Nor is it possible to produce a state 105 of fluorescent emission below the paper by increasing the thickness of the layer of fluorescent particles P in Figure 2, because the intrinsic brilliance of the fluorescent substances used cannot be increased ad 110 libitum by increasing the volume of the applied layer, such increase merely leading to a saturation value.

In the apparatus shown in Figure 3, the bank-note B spread in a plane is passed 115 between a light source 2 and a photoreceiver 3 by means of a suitable device 1. The device 1 comprises a pair of rubber belts 4a, 4b, 5a, 5b carrying the bank-note along its longitudinal edges and moving it 120 in the direction of the arrow in Figures 3 and 4 while in its spread condition. The drive of the rubber belts 4a, 4b, 5a and 5b is not shown in detail. The invention is not restricted to this particular device for 125 moving the bank-note past the light source and the photo-receiver; other devices may be used, such as glass plates placed one upon the other or vacuum gripping means or the like. A colour filter 6 is arranged 130

70

75

between the bank-note B and the light source 2, said colour filter being chosen to be of a very narrow bandwidth appropriate to the excitation spectrum required for

the fluorescent substances used.

The photo-receiver 3 comprises a filter 7 and a photo-senstive structural element The filter 7 is selected to be of very narrow band-width appropriate to the spectrum of emission of the fluorescence particles used. The filter 7 may be omitted if the photo-sensitive structural element employed has itself a suitable narrow band Another photo-receiver 9 characteristic. 15 is arranged on the same side of the banknote B as the light source 2, said photo-receiver 9 comprising a filter 10 and a photo-sensitive structural element 11. The filter 10 is again selected to be of such narrow band-width that it allows only the fluorescence radiation FS to pass.

Below the bank-note B and in the path of the exciting radiation AS there is arranged a third photo-receiver 12 comprising a filter 13 and a photo-senstive structural element 14. The filter 13 is selected to pass only the spectrum AS necessary for excitation.

It may be arranged, by suitable optical

measures such as the fitting of diaphragms, that the fields of view of the lamp 2 and the photo-receivers 3, 9 and 12 embrace one and the same narrow srip over the entire width of the bank-note B. Alternatively the fields of view of the lamp 2 and the photo-receivers 3, 9 and 12 could embrace a narrow strip extending over the entire length of the bank-note.

The photo-receiver 3 is arranged to be inclined with respect to the plane of the bank-note to make room for the fitting of the photo-receiver 12, while the photoreceiver 9 at the other side of the bank-note is inclined so as not to interfere with the light source 2 and the filter 6. The filter 45 6 preferably allows only UV radiation to pass because, on the one hand, very many substances may be excited to fluoresce by UV radiation and, on the other hand, the transparency of paper in the UV spectral range is very low. The outputs of the photo-receivers 3, 11, 12 are connected with a control unit 19 via electric conductors 15, 16 and 17.

The block circuit diagram shown in 55 Figure 5 represents the control unit 19 in connection with the photo-sensitive structural elements 8, 11 and 14. Respectively series-connected to each of the photosensitive structural elements in a preampli-60 fier 20. The preamplifiers 20 respectively associated with the sensitive structural elements 8 and 11 are connected to a coincidence circuit 23 via lines 21 and 22, said coincidence circuit 23 being connected to a counting mechanism 25 via a line 24. The

output of the counting mechanism 25 is connected to a trigger mechanism 27 via a line 26, an acceptance signal a or a rejection signal z appearing at the outputs of said trigger mechanism 27, which signals serve to operate electromagnetic devices diverting a rejected bank-note B from the conveyor path. Alternatively, the signals a and z may also be utilized to actuate optical or acoustic signalling devices. The preamplifter series-connected to the photo-sensitive structural element 14 is connected to an amplitude discriminator 29 via a line 28, the upper the shold O of which is adjustable through suitable means such as a rotary knob 30 and the lower threshold U of which is adjustable through suitable means such as a rotary knob 31. The output of the discriminator 29 is connected to the trigger mechanism 27 via a line 32

The examination of the bank-note will by be described. If the bank-note is now be described. passed between the light source 2 and the photo-receiver 9 on the one side, and the photo-receivers 3 and 12 on the other side, the fibres incorporated in the bank-note successively enter the fields of view of the light source and the photo-receiver which fields of view, in the case of the embodiment shown, coincide. At the moment considered in Figures 3 and 4, the three fibres F are in the common field of view. At the outputs of the photo-receivers 3 and 9 there appear signals which are amplified in the pre-amplifiers 20 and checked as to 100 their coincidence in the coincidence circuit 23. If coincident signals are present, then the output signal fed to the counting mechanism 25 via the line 24 switches the counting mechanism 25 onward by one unit. Such 105 coincident signals occur several times, in relation to the number of fibres present, when the bank-note spread-oul in a plane is passed through. When a predetermined minimum number is reached, an output sig- 110 nal appears at the output of a counting mechanism 25 provided with a preset arrangement which is passed to the trigger mechanism 27 via line 26.

Although the transparency of the bank- 115 note paper is poor for the spectral range of the exciting radiation AS, the signal appearing at the output of the photoelement 14, after amplification by the preamplifier 20, is still required to have a 120 minimum level, which is above the lower threshold U adjusted in the discriminator 29. Thus it is possible to recognise a type of paper having a wrong density. On the other hand, in the case of a crack or an 125 inaccurate seam the exciting radiation passes through the filter 13 into the photoelement 14 with small reduction in intensity. The corresponding signal will thus be above the upper threshold O of the discriminator 130

20

The range of transparency of the discriminator 29 is adjusted to be such that cracks, inaccurate seams, lacking water marks or missing safety threads, wrong density of papers or areas of adhesion are recognised in the paper. If the signal applied via line 28 is above the upper threshold O or below the lower threshold U, a signal is supplied to the trigger mechanism 27 via line 32 which is effective to cause final rejection of the piece of paper tested as a bank-note.

By the method and apparatus of the invention it is possible to carry out a test for the authenticity of a piece of paper in a simple manner and without having to form on a photo-receiver an exact image of all the details of the piece of paper.

WHAT WE CLAIM IS:-

1. A method of testing the authenticity of pieces of paper containing fluorescent material, in which the paper is moved past a light source the radiation of which excites the fluorescent particles, and the fluorescence radiation emanating on that side of the paper which is averted from the light source is measured by means of a photo-receiver which is sensitive only to that radiation, the result of the test being indicated by the output of the photoreceiver.

2. A method in accordance with claim 1, wherein the fluorescence radiation ema-35 nating from that side of the paper which faces the light source is measured by means of a photo-receiver sensitive only to that radiation, the result of the test being indicated by the outputs of both of the photoreceivers.

3. A method in accordance with claim 1 or 2, wherein exciting radiation which passes through the paper is measured by means of a photo-receiver sensitive only to 45 that exciting radiation, the output of which photo-receiver provides a further test result for the acceptance or rejection of the paper.

4. A method in accordance with any of claims 1 to 3, wherein signals derived from the fluorescence radiation emanating from that side of the paper which is averted from the light source are counted, the piece of paper passing the test provided with a predetermined minimum number of signals is 55 reached.

5. A method in accordance with any of claims 2 to 4, wherein is measured the coincident occurrence of signals derived from the fluorescence radiation emanating from 60 both sides of the paper.

6. A method in accordance with claim 5, wherein the coincident signals are counted, the piece of paper passing the test pro-vided that a predetermined minimum num-65 ber of signals is reached.

7. A method in accordance with any one of claims 1 to 6, wherein the received signals due to exciting radiation passing through the paper are discriminated, and rejection of the piece of paper indicated when the lower threshold is not reached or the

upper threshold is exceeded.

8. A method in accordance with any one of claims 1 to 7, wherein the excitation and the registration of the radiation of fluorescence take place simultaneously.

A method in accordance with any one of the claims 1 to 3, wherein the excitation and the registration of the fluorescence radiation are effected at time intervals from each other.

10. Apparatus for testing the authenticity of pieces of paper containing fluorescent material, with the aid of a light source the radiation of which excites the fluorescent particles, and including means for moving the paper spread-out in a plane past the light source, the light source and a photo-receiver senstive to the fluorescence a photo-receiver sensure to the morescence radiation emitted from the particles being arranged on opposite sides of the plane.

11. Testing apparatus in accordance with claim 10, wherein a second photo-

receiver sensitive to the emitted fluorescence radiation is arranged on the light source 95

side of the plane.

12. Testing apparatus in accordance with claim 10 or 11, wherein a photoreceiver sensitive to the exciting radiation is arranged on the side of the plane opposite 100 that of the light source.

13. Testing apparatus in accordance with any one of claims 10 to 12, wherein the fields of view of the light source and the photo-receiver for fluorescence radi- 105 ation arranged on the other side of the paper coincide.

14. Testing apparatus in accordance with any one of claims 10 to 13, wherein the fields of view of the two photo-receivers 110 sensitive only to the fluorescence radiation coincidence.

15. Testing apparatus in accordance with any one of the claims 10 to 14, wherein the fields of view of light source and photo- 115 receiver comprise narrow strips extending

length-wise or width-wise of the paper.

16. Testing apparatus in accordance with any one of the claims 10 to 15, comprising a photo-receiver composed of 120 photo-sensitive structural elements and narrow wave-band filters.

17. Testing apparatus in with any one of claims 10 to 16, wherein a narrow band filter is arranged between 125 according the light source and the plane in which the paper is moved, said filter passing only the exciting radiation.

18. Testing apparatus in accordance with any one of claims 10 to 17, wherein 130

3DOCID: <GB___1326665A__I_>

the outputs of the photo-receivers are connected via electric conductors to a control

19. Testing apparatus in accordance with claim 18, wherein the control unit includes a coincidence circuit, a counting mechanism, a discriminator circuit and a trigger mechanism.

trigger mechanism.

20. A method or apparatus for testing
the authenticity of pieces of paper substan-

tially as herein described with reference to the accompanying drawings. ARTHUR R. DAVIES, Chartered Patent Agents, 27, Imperial Square, Cheltenham.
